Boolean Differential Calculus
The *Synthesis Lectures on Digital Circuits and Systems* series is comprised of 50- to 100-page books targeted for audience members with a wide-ranging background. The Lectures include topics that are of interest to students, professionals, and researchers in the area of design and analysis of digital circuits and systems. Each Lecture is self-contained and focuses on the background information required to understand the subject matter and practical case studies that illustrate applications. The format of a Lecture is structured such that each will be devoted to a specific topic in digital circuits and systems rather than a larger overview of several topics such as that found in a comprehensive handbook. The Lectures cover both well-established areas as well as newly developed or emerging material in digital circuits and systems design and analysis.

SYNTHESIS LECTURES ON DIGITAL CIRCUITS AND SYSTEMS #52
ABSTRACT

The Boolean Differential Calculus (BDC) is a very powerful theory that extends the basic concepts of Boolean Algebras significantly. Its applications are based on Boolean spaces \( \mathbb{B} \) and \( \mathbb{B}^n \), Boolean operations, and basic structures such as Boolean Algebras and Boolean Rings, Boolean functions, Boolean equations, Boolean inequalities, incompletely specified Boolean functions, and Boolean lattices of Boolean functions. These basics, sometimes also called switching theory, are widely used in many modern information processing applications.

The BDC extends the known concepts and allows the consideration of changes of function values. Such changes can be explored for pairs of function values as well as for whole subspaces. The BDC defines a small number of derivative and differential operations. Many existing theorems are very welcome and allow new insights due to possible transformations of problems. The available operations of the BDC have been efficiently implemented in several software packages.

The common use of the basic concepts and the BDC opens a very wide field of applications. The roots of the BDC go back to the practical problem of testing digital circuits. The BDC deals with changes of signals which are very important in applications of the analysis and the synthesis of digital circuits. The comprehensive evaluation and utilization of properties of Boolean functions allow, for instance, to decompose Boolean functions very efficiently; this can be applied not only in circuit design, but also in data mining. Other examples for the use of the BDC are the detection of hazards or cryptography. The knowledge of the BDC gives the scientists and engineers an extended insight into Boolean problems leading to new applications, e.g., the use of Boolean lattices of Boolean functions.

Introduction

Boolean (two-valued, dual, binary) systems have a long history and tradition in science and technology. In our daily life we normally meet the decimal number system that uses ten digits which get their meaning in a number based on powers of 10. The representation by means of dual numbers only needs two digits 0 and 1. Instead of the powers of 10 now powers of 2 are taken into consideration.

Arithmetic using dual numbers has been completely presented by G. W. Leibniz (Explanation de l’Arithmétique Binaire (Histoire de l’Academie Royale des Sciences 1703), published in Paris 1705). In 1854, George Boole published a precedent-setting book which describes a system that formalizes the laws of correct thinking (Boole [1854, Reprint: 2010]). He was working with the two values true and false and created a propositional calculus which today is called Boolean Algebra. The next famous name is Claude Shannon. He proved that Boolean Algebra and dual arithmetic could be used to simplify the arrangement of the electromechanical relays that were used then in telephone call routing switches. Next, he expanded this concept proving that it would be possible to use arrangements of relays to solve problems in Boolean Algebra. Using this property of electrical switches to implement logic is the fundamental concept that underlies all electronic digital computers. Shannon’s work became the foundation of digital circuit design. The restriction to only two digits and the utilization of the ideas of Boole and Shannon are the keys that Conrad Zuse was able to realize the first computer.

Since then a gigantic building of theory and applications has been created that requires careful and comprehensive studies. Switching theory deals with Boolean structures using the elements of $\mathbb{B} = \{0, 1\}$ and covers a wide field of applications. However, there are applications which require information about the effects of changing the values of variables and functions. One of them is the test of combinational circuits. Investigations of this topic by Reed [1954], Huffman [1958], and Akers [1959] can be seen as the roots of the Boolean Differential Calculus (BDC).

Basics of the BDC were published by A. Thayse and his group (Davio et al. [1978], Thayse [1981]). Comprehensive studies were carried out by a research group at the Chemnitz University of Technology where the authors are coming from. Results of this research were published in German in the monograph about the Boolean Differential Calculus by Bochmann and Posthoff [1981]. Chapters in Posthoff and Steinbach [2004] and Sasao and Butler [2010] summarize the main definitions of the BDC and present some selected applications. An extensive article about the BDC and its applications (Steinbach and Posthoff [2010a]) was published in the Journal of Computational and Theoretical Nanoscience.
The BDC was successfully applied in the last years to solve many problems. This success is not only based on the theoretical background of the BDC, but also on the efficient implementation of the derivative operations as part of the XBOOLE library as shown by Steinbach [1992]. The book Steinbach and Posthoff [2009] contains many examples and exercises where the BDC and the XBOOLE-Monitor (freely available over the Internet) were efficiently used. This book also provides the solution for all exercises and supplements the textbook Posthoff and Steinbach [2004].

The naming of several concepts of the BDC has been based on formal analogies with the differential and integral calculus for real numbers and functions. However, it should not be forgotten that we are dealing with finite algebraic structures without concepts like limits etc. Nevertheless, these analogies can be extended to create a Boolean Integral Calculus. The basics of this inverse calculus were already provided in the monograph Bochmann and Posthoff [1981]. The Boolean Integral Calculus and especially methods to solve Boolean differential equations have been presented in the Ph.D. thesis of Steinbach [1981]. The book Steinbach and Posthoff [2013a], published by Morgan & Claypool, explains these methods, their practical calculations using the XBOOLE-Monitor, and demonstrates many applications.

We also can consider the possibility of changing the values of variables and functions by using differentials of variables $dx_i$ and functions $df_j$. Using such differentials we get an excellent possibility to describe graphs and model their properties.

The BDC basically deals with changing the values of Boolean functions. Extensions to multivalued variables and functions are given in Yanushkevich [1998], and in combination with binary concepts already in Bochmann and Posthoff [1981]. Some comments according to this approach are repeated in Bochmann [2008].

Replacing a single Boolean function by a lattice of such functions is an important source for finding optimal solutions, especially in circuit design. Therefore, derivative operations of lattices become a new problem. A recent research result of Steinbach and Posthoff [2013b, 2015] and Steinbach [2013] is the extension of the BDC to lattices of Boolean functions. These extensions and promising applications are included into this presentation of the Boolean Differential Calculus.

It is our aim to present the theory of the BDC and many applications in a well understandable manner. The classification of the single derivatives as a special case of the vectorial derivatives contributes to this aim. The reader should always try to understand the concepts and do as many examples as possible. To this end we added several exercises at the end of the chapters and give the associated solutions in the final chapter. We hope that this book helps the readers to solve their relevant problems more efficiently.

Bernd Steinbach and Christian Posthoff
December 2016
CHAPTER 1

Basics of Boolean Structures

1.1 LATTICES AND FUNCTIONS

We use the set \( \mathbb{B} = \{0, 1\} \) with two different elements 0 and 1 as the initial point. An order relation \( \leq \) can be defined as follows:

\[
0 \leq 0, \quad 0 \leq 1, \quad 1 \leq 1.
\]

This order relation allows the finding of the minimum and the maximum of any two elements:

\[
\min(0, 0) = 0, \quad \min(0, 1) = 0, \quad \min(1, 0) = 0, \quad \min(1, 1) = 1,

\max(0, 0) = 0, \quad \max(0, 1) = 1, \quad \max(1, 0) = 1, \quad \max(1, 1) = 1.
\]

Instead of minimum and maximum the operation signs \( \wedge \) and \( \vee \) are used, together with the names conjunction and disjunction instead of minimum and maximum:

\[
\min(x, y) = x \wedge y, \quad \max(x, y) = x \vee y.
\]

This results in Table 1.1.

**Table 1.1:** Conjunction and disjunction

<table>
<thead>
<tr>
<th>( x_1 )</th>
<th>( x_2 )</th>
<th>( x_1 \wedge x_2 )</th>
<th>( x_1 \vee x_2 )</th>
<th>( \min(x_1, x_2) )</th>
<th>( \max(x_1, x_2) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

It means that we can start with the order relation \( \leq \) and define the conjunction and the disjunction as the minimum and the maximum of two values. It is, however, also possible to define these two operations \( \wedge \) and \( \vee \) by means of Table 1.1 and take the conjunction for the minimum and the disjunction for the maximum. This is justified because in each row the value \( x_1 \wedge x_2 \) is less than the value of \( x_1 \vee x_2 \). The two approaches are completely equivalent.
1. BASICS OF BOOLEAN STRUCTURES

Now we formulate the following laws.

1. **Commutativity:**
   \[ x_1 \lor x_2 = x_2 \lor x_1, \quad (1.1) \]
   \[ x_1 \land x_2 = x_2 \land x_1, \quad (1.2) \]

2. **Associativity:**
   \[ x_1 \lor (x_2 \lor x_3) = (x_1 \lor x_2) \lor x_3 = x_1 \lor x_2 \lor x_3, \quad (1.3) \]
   \[ x_1 \land (x_2 \land x_3) = (x_1 \land x_2) \land x_3 = x_1 \land x_2 \land x_3, \quad (1.4) \]

3. **Idempotence:**
   \[ x \lor x = x, \quad (1.5) \]
   \[ x \land x = x, \quad (1.6) \]

4. **Absorption:**
   \[ x_1 \lor (x_1 \land x_2) = x_1, \quad (1.7) \]
   \[ x_1 \land (x_1 \lor x_2) = x_1. \quad (1.8) \]

The absorption laws connect the two operations \( \land \) and \( \lor \). The other laws include only one operation.

Table 1.2 shows the proof of one of these laws; this table method is not difficult and very typical. We enumerate all the vectors of \( B \times B \) and calculate the left and the right side of the equation. The equality of the first and the last column show that the equation is correct.

<table>
<thead>
<tr>
<th>( x_1 )</th>
<th>( x_2 )</th>
<th>( x_1 \land x_2 )</th>
<th>( x_1 \lor (x_1 \land x_2) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

These four laws define the algebraic structure of a lattice.

Now we extend this concept and build vectors with \( n \) components where each component will take one of these two values.

**Definition 1.1 Boolean Space.** For \( B = \{0, 1\} \),

\[
B^n = \{ x | x = (x_1, x_2, \ldots, x_{n-1}, x_n), x_i \in B, \ i = 1, \ldots, n \} \tag{1.9}
\]

is the set of all binary vectors of length \( n \), the *Boolean space* \( B^n \).

It can also be understood as the cross product

\[
B^n = B \times \ldots \times B = \{ x | x = (x_1, \ldots, x_n), x_i \in B, \ i = 1, \ldots, n \}.
\]

\( n \) times
Here are two small examples:
\[
\mathbb{B}^2 = \{(00), (01), (10), (11)\}, \\
\mathbb{B}^3 = \{(0000), (0001), (0010), (0011), (0100), (0101), (0110), (0111), \\
(1000), (1001), (1010), (1011), (1100), (1101), (1110), (1111)\}.
\]

Since there are \(n\) components and each component can take on two values, \(\mathbb{B}^n\) contains \(2^n\) different elements (vectors).

For \(\mathbb{B}^n\) we introduce a partial order relation in the following way: for \(x = (x_1, \ldots, x_n)\) and \(y = (y_1, \ldots, y_n)\) the \(\leq\) of \(\mathbb{B}\) has to be applied for each component:
\[
x \leq y \text{ if and only if } x_i \leq y_i \text{ for } i = 1, \ldots, n.
\]

The effect of this definition explains the name partial order: for some vectors we get \(x \leq y\), for instance \((0010) \leq (1011)\), but for other vectors it can be possible that there we have neither \(x \leq y\) nor \(y \leq x\), for instance \(x = (1001), y = (0110)\). These vectors are not comparable.

Nevertheless, this relation allows again the definition of the minimum and the maximum of two vectors by applying the conjunction and the disjunction of \(\mathbb{B}\) component by component:
\[
\begin{align*}
x &= (10011100), \\
y &= (00110101), \\
x \land y &= (00010100), \\
x \lor y &= (10111101).
\end{align*}
\]

The properties of a lattice are again satisfied, \((\mathbb{B}^n, \land, \lor)\) is also a lattice.

As we can see by this example, neither the minimum nor the maximum must be equal to one of the given vectors. When all the vectors of \(\mathbb{B}^n\) are included, then the minimum is equal to the vector \(0 = (0, 0, \ldots, 0)\), the maximum is equal to \(1 = (1, 1, \ldots, 1)\), and these two vectors are also elements of \(\mathbb{B}^n\).

Now a subset \(S\) of \(\mathbb{B}^n\) is considered: \(S \subset \mathbb{B}^n\). The conjunction of all elements of \(S\) is the minimum \(\min(S)\) of \(S\), the disjunction of all elements of \(S\) is the maximum \(\max(S)\) of \(S\). The vectors \(\min(S)\) and \(\max(S)\) can be an element of \(S\), but not necessarily. If the conjunction and the disjunction of any two elements of \(S \subset \mathbb{B}^n\) are again elements of \(S\) then \(S\) is a sublattice of \(\mathbb{B}^n\).

For the representation of Boolean functions a second relation will be considered, an order relation where all the elements are comparable. The easiest way is the use of the decimal equivalent of a dual vector. When \(n\) is set to 3, for instance, then we get
\[
(000), (001), (010), (011), (100), (101), (110), (111)
\]
in this order, and this corresponds to the dual representation of the numbers 0, 1, 2, 3, 4, 5, 6, 7. It is often named lexicographic order. Very often such vectors will be used as the argument vectors of Boolean functions, and it is possible to assign the variables \(x_1, x_2, x_3\) to such vectors.
6  1. BASICS OF BOOLEAN STRUCTURES

Now everything is prepared to define Boolean functions.

**Definition 1.2  Boolean Function.** Each unique mapping from \( B^n \) into \( B \) is a *Boolean function* of \( n \) variables.

Since \( B^n \) has \( 2^n \) elements, there are \( 2^{2^n} \) different functions of \( n \) variables. Important are the elementary functions for \( n = 1 \) and \( n = 2 \). We start with \( n = 1 \). Then \( 2^n = 2 \) and \( 2^{2^n} = 4 \). Therefore we have two values for the single variable and four different functions. Table 1.3 shows the four different functions of one variable \( x \), \( f_1(x) \) will be used for the respective function values:

\[
\begin{align*}
  f_0(x) &= 0(x), \\
  f_1(x) &= x, \\
  f_2(x) &= \overline{x}, \\
  f_3(x) &= 1(x).
\end{align*}
\]

**Table 1.3:** Boolean functions of one variable

<table>
<thead>
<tr>
<th>( x )</th>
<th>( f_0 )</th>
<th>( f_1 )</th>
<th>( f_2 )</th>
<th>( f_3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

When we read the function values vertically, then we see the binary vectors of \( B^2 \):

\[
( f_i(0), f_i(1)) : (00), (01), (10), (11). 
\]

The functions \( 0(x) \) and \( 1(x) \) are constant \( = 0 \) and \( = 1 \), resp., the variable \( x \) indicates that these functions depend on one variable.

The function \( f_2(x) \) converts the two values into each other; it is called *negation* and indicated by a line above the variable, i.e., by \( \overline{x} \):

\[
\overline{0} = 1, \quad \overline{1} = 0. \tag{1.10}
\]

*Literal* can be used as a *common name* for variables and negated variables. The twofold use of the negation reproduces the original value:

\[
\overline{\overline{x}} = x. \tag{1.11}
\]

The functions of two variables can be seen in Table 1.4. The set of all possible Boolean functions of two variables is equal to \( B^4 \) and satisfies the axioms of a lattice.

There are two *constant* functions: \( f_0(x) = 0(x_1, x_2) \) and \( f_{15}(x_1, x_2) = 1(x_1, x_2) \). The function \( f_1(x_1, x_2) \) is already known as *conjunction*:

\[
f_1(x_1, x_2) = x_1 \land x_2. \tag{1.11}
\]
1.1. LATTICES AND FUNCTIONS

Table 1.4: Boolean functions of two variables

</tbody>
</table>

Very often $\land$ is omitted, and we simply write $f_1(x_1, x_2) = x_1 \cdot x_2$. The main property of this function: it is only equal to 1 if both arguments are equal to 1 ($x_1 = x_2 = 1$). This has been seen already when the minimum for $B$ has been defined.

We are also familiar with $f_7(x_1, x_2)$, the disjunction:

$$f_7(x_1, x_2) = x_1 \lor x_2.$$  \hspace{1cm} (1.12)

The important property of this function: $f_7(x_1, x_2) = x_1 \lor x_2 = 0$ only holds for $x_1 = 0$ and $x_2 = 0$ (remember the maximum for $B$).

Two functions are very appropriate to indicate the inequality and the equality of the arguments (see Table 1.4) by their function values:

$$f_6(x_1, x_2) = x_1 \oplus x_2 \quad \text{(antivalence)}$$  \hspace{1cm} (1.13)

and

$$f_9(x_1, x_2) = x_1 \odot x_2 \quad \text{(equivalence)}.$$  \hspace{1cm} (1.14)

It can be seen that the vector of the antivalence (0110) can be transformed into the vector of the equivalence (1001) and vice versa by means of the negation:

$$\overline{x_1 \odot x_2} = x_1 \oplus x_2, \quad \overline{x_1 \oplus x_2} = x_1 \odot x_2.$$  \hspace{1cm} (1.15)

Two more functions are very often used in circuit design:

$$f_8(x_1, x_2) = \overline{x_1 \lor x_2} = \overline{x_1} \land \overline{x_2}$$  \hspace{1cm} (1.16)

and

$$f_{14}(x_1, x_2) = \overline{x_1 \land x_2} = x_1 \lor x_2.$$  \hspace{1cm} (1.17)

Each reader must ensure that he knows all these functions and can use them properly. It can be taken into consideration that the length of binary vectors representing a Boolean function always is a power of 2: $2^1 = 2$, $2^2 = 4$, $2^3 = 8$, …

The main problem that must be addressed for many applications is the exponential complexity: for $n = 3$ there are already $2^3 = 8$ = 256 functions of 3 variables, etc.
In order to cope with these problems formulas will be used. Each correct formula must be built by means of the following steps.

**Definition 1.3 Construction of Formulas.**

1. The constants 0 and 1 and the single variables $x_1, \ldots, x_n$ are formulas.
2. If $F$ is a formula then $\overline{F}$ is also a formula.
3. If $F_1$ and $F_2$ are formulas then
   
   $$(F_1 \land F_2), \quad (F_1 \lor F_2), \quad (F_1 \oplus F_2), \quad \text{and} \quad (F_1 \odot F_2)$$

   are also formulas.
4. Each formula can be built when the second and the third rule are applied finitely many times.

**Example 1.4 Construction of a Formula of Four Variables.**

- We start with $x_1, x_2, x_3$ and $x_4$.
- Thereafter, we build $F_1 = (x_1 \lor x_2)$ and $F_2 = (x_3 \oplus x_4)$.
- Next, we set $F_3 = \overline{F_2}$.
- Finally:
  
  $$f(x_1, x_2, x_3, x_4) = (F_1 \land F_3) = (x_1 \lor x_2) \land (\overline{x_3} \oplus x_4).$$

The formula is a nice abbreviation, however, it does not really show the function values. In order to find these values we must go back to the 16 possible combinations of values and calculate each value of $F(x_1, x_2, x_3, x_4)$ by means of the respective parts of the formula. And this brings back the problem of very large tables; see Table 1.5 for the example.

**Example 1.5 Lattice of Boolean Functions.** The functions $f_1(x_1, x_2, x_3)$, $f_2(x_1, x_2, x_3)$, and $f_3(x_1, x_2, x_3)$ will be given as follows:

- $f_1(x_1, x_2, x_3) : \begin{pmatrix} 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \end{pmatrix}$,
- $f_2(x_1, x_2, x_3) : \begin{pmatrix} 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \end{pmatrix}$,
- $f_3(x_1, x_2, x_3) : \begin{pmatrix} 1 & 0 & 1 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$.

</tbody>
</table>

It can be seen that \( f_1 \leq f_2 \), \( f_1 \leq f_3 \) and \( f_2 \leq f_3 \). This means that

\[
\min(f_1, f_2, f_3) = f_1, \quad \max(f_1, f_2, f_3) = f_3.
\]

The \( \land \) and the \( \lor \) of any of these three functions is again one of these three functions. The set \( \{f_1, f_2, f_3\} \) is closed with regard to these two operations and therefore a lattice.

Another possibility is the following ternary vector:

\[(011 - 0 - 10)\]

Sometimes it is also written as

\[(011 \Phi 0 \Phi 10)\]

The dash (–) or the \( \Phi \) can be arbitrarily replaced by 0 or 1, in this way we get four functions that satisfy the axioms of a lattice. In circuit design such a lattice is generated by don't-care conditions.

Now we split the algebraic background into two directions: Boolean Algebras and Boolean Rings.
10 1. BASICS OF BOOLEAN STRUCTURES

1.2 BOOLEAN ALGEBRAS

We have already considered the four properties of a lattice, now we can add some more laws. The verification of these laws follows the same procedure as before, we enumerate all possibilities and check the left and the right side of the equations. The variables of the next formulas always take their values from $\mathbb{B}$, but all of them can be replaced by vectors when the operations are performed component by component. The 0 must be replaced by the vector $\mathbf{0} = (0 \ldots 0)$ and the 1 by $\mathbf{1} = (1 \ldots 1)$ when vector operations are computed:

1. **Distributivity:**
   \[
   x_1 \lor (x_2 \land x_3) = (x_1 \lor x_2) \land (x_1 \lor x_3) ,
   \]
   \[
   x_1 \land (x_2 \lor x_3) = (x_1 \land x_2) \lor (x_1 \land x_3) ,
   \]
   (1.18)
   (1.19)

2. **Neutral elements:**
   \[
   0 \lor x = x ,
   \]
   \[
   1 \land x = x ,
   \]
   (1.20)
   (1.21)

3. **Complement:**
   \[
   x \lor \overline{x} = 1 ,
   \]
   \[
   x \land \overline{x} = 0 ,
   \]
   (1.22)
   (1.23)

4. **De Morgan’s Laws:**
   \[
   \overline{x_1 \land x_2} = \overline{x_1} \lor \overline{x_2} ,
   \]
   \[
   \overline{x_1 \lor x_2} = \overline{x_1} \land \overline{x_2} .
   \]
   (1.24)
   (1.25)

Both these four laws and the four laws of a lattice (see page 4) remain true when the operations $\lor$ and $\land$ are exchanged. When these four laws are added to the laws of a lattice then all the axioms of a **Boolean Algebra** are satisfied. As a summary we get the following.

**Theorem 1.6 Boolean Algebras.** *The structures*

\[
(\mathbb{B}, \land, \lor, \neg, 0, 1), \ (\mathbb{B}, \lor, \land, \neg, 1, 0), \ (\mathbb{B}^n, \land, \lor, \neg, 0, 1), \ and \ (\mathbb{B}^n, \lor, \land, \neg, 1, 0)
\]

*are Boolean Algebras.*

It is possible that different formulas describe the same function. This is already indicated by the transformation rules from above. It will be later on a problem to find formulas that satisfy a given criterion.

Up until now we reached the following point:

- a Boolean function can be defined by a table; and
- we can find the function table when a formula has been given.

We still need a possibility to find a formula for a function which is given by a table. We go back to Table 1.5 and consider the lines with the function value 1 for

\[
f = (x_1 \lor x_2) \land (x_3 \oplus x_4) .
\]
We use, for instance, the first row \((x_1,x_2,x_3,x_4) = (0100)\) and assign a negated variable to the value 0 and a non-negated variable to the value 1. These (negated or non-negated) variables are combined by \(\land\). For the given vector we get \(\overline{x}_1 \overline{x}_2 \overline{x}_3 \overline{x}_4\). In this way the conjunction will result in the value 1 exactly for the given vector; for the other vectors of \(B^4\) the conjunction results in 0. This will be done for all the given lines of the table, the resulting six conjunctions are combined by \(\lor\), the resulting disjunction of conjunctions is called the **disjunctive normal form**. It is uniquely defined except the order of the conjunctions. This, however, does not matter because of the commutativity of \(\lor\). The other vectors which are not in the table result in \(f = 0\). In this way we get a formula for the representation of a Boolean function which is given by Table 1.6:

\[
f(x_1, x_2, x_3, x_4) = \overline{x}_1 \overline{x}_2 \overline{x}_3 \overline{x}_4 \lor \overline{x}_1 x_2 x_3 x_4 \lor x_1 \overline{x}_2 \overline{x}_3 \overline{x}_4 \lor \overline{x}_1 \overline{x}_2 x_3 x_4 \lor x_1 x_2 \overline{x}_3 x_4 \lor x_1 x_2 x_3 x_4.
\]  

(1.26)

Special denominations are sometimes necessary for the constant functions which are equal to 0 or 1 for all possible vectors \(x\). If it is necessary to show the variables that are important in a given context then we write \(0(x_1, x_2, x_3, x_4)\) or \(1(x_1, x_2, x_3, x_4)\); if the context is clear we might simply use 0 or 1 for these functions.

A second approach results in the **conjunctive normal form**. We select the binary vectors which are assigned to the function value 0 (see Tables 1.5 and 1.7). Here the non-negated variables are used for the value 0 in the vector, the negated variables are used when the component of the vector is equal to 1. The resulting literals are combined by \(\lor\). Each disjunction is equal to 0 for the respective binary vector. The resulting disjunctions are combined by \(\land\). Since the conjunction with 0 always results in 0, finally the conjunction of all these disjunctions produces all the values 0 of \(f\). In this way we have built the **conjunctive normal form**. It is also uniquely defined except the order of the disjunctions:
12 1. BASICS OF BOOLEAN STRUCTURES

\[ f(x_1, x_2, x_3, x_4) = (x_1 \lor x_2 \lor x_3 \lor x_4)(x_1 \lor x_2 \lor x_3 \lor \overline{x}_4)(x_1 \lor x_2 \lor x_3 \lor x_4) \\
(x_1 \lor x_2 \lor \overline{x}_3 \lor x_4)(x_1 \lor \overline{x}_2 \lor x_3 \lor x_4)(x_1 \lor \overline{x}_2 \lor x_3 \lor x_4) \\
(\overline{x}_1 \lor x_2 \lor x_3 \lor x_4)(\overline{x}_1 \lor x_2 \lor \overline{x}_3 \lor x_4)(\overline{x}_1 \lor x_2 \lor x_3 \lor \overline{x}_4) \]

If there is a given Boolean function and we specify the value of one variable the result is a subfunction.

</tbody>
</table>

**Definition 1.7 Cofactors.** Let \( f(x_1, x_2, \ldots, x_n) = f(x_i, x_1) \) be a function of \( n \) variables.

Then the negative cofactor

\[ f^0_{x_i}(x_1) = f(x_i = 0, x_1) \tag{1.28} \]

and the positive cofactor

\[ f^1_{x_i}(x_1) = f(x_i = 1, x_1) \tag{1.29} \]

are the two subfunctions with regard to \( x_i \).

The resulting subfunctions do not depend on the respective variable anymore.

**Example 1.8 Cofactors With Regard to \( x_1 \).** We use the function (1.27) as an example and set \( x_1 = 0 \):
For $x_1 = 1$ the following function comes into existence:

$$f^1_{x_1}(x_1) = f(x_1 = 1, x_2, x_3, x_4) = (x_2 \lor x_3 \lor x_4)(x_2 \lor \overline{x}_3 \lor x_4)
(x_2 \lor x_3 \lor \overline{x}_4)(\overline{x}_2 \lor x_3 \lor \overline{x}_4)(\overline{x}_2 \lor x_3 \lor x_4).$$

It can be seen that some vectors of the function table are selected, all the vectors with a special value in the first component.

We go back to the disjunctive normal form (see (1.26)) and use the distributive law after the collection of the disjunctions of the normal form according to $x_1$:

$$f(x_1, x_2, x_3, x_4) = \overline{x}_1 f^0_{x_1} \lor x_1 f^1_{x_1} = \overline{x}_1 f^0_{x_1} \oplus x_1 f^1_{x_1}$$

and has been introduced by C. Shannon. $f^0_{x_1}$ and $f^1_{x_1}$ are the two cofactors from above. Each Boolean function can be decomposed using the following.

**Theorem 1.9 Shannon Decomposition.** Each Boolean function $f(x) = f(x_1, x)$ can be represented by

$$f(x_1, x_1) = \overline{x}_1 f(x_1 = 0, x_1) \lor x_1 f(x_1 = 1, x_1)$$

$$= \overline{x}_1 f(x_1 = 0, x_1) \oplus x_1 f(x_1 = 1, x_1)$$

for any $x_1 \in x$, where $x_1 = x \setminus x_1$.

The cofactors $f^0_{x_1}(x_1) = f^0_{x_1}(x_2, x_3, x_4)$ and $f^1_{x_1}(x_1) = f^1_{x_1}(x_2, x_3, x_4)$ of (1.31) depend on $x_2, x_3, x_4$. As a border case it can happen that $f^0_{x_1}(x_1) = f^1_{x_1}(x_1)$. This is an example for the independence of a function of a variable because we get step-by-step

$$f(x_1, x_2, x_3, x_4) = \overline{x}_1 f^0_{x_1}(x_1) \lor x_1 f^1_{x_1}(x_1)
= (\overline{x}_1 \lor x_1) f^0_{x_1}(x_1)
= f^0_{x_1}(x_2, x_3, x_4).$$
14  1. BASICS OF BOOLEAN STRUCTURES

This independence can also be seen when we go back to Table 1.4. Here we get for \( f_3(x_1, x_2) \):
\[
f_3(x_1, x_2) = x_1 \overline{x}_2 \lor x_1 x_2 = x_1 \overline{(x_2 \lor x_2)} = x_1 .
\]
We get a formula without \( x_2 \), nevertheless the function \( f_3 \) is a function of \( x_1 \) and \( x_2 \).

Functions also can be embedded into larger spaces using one additional variable. The reverse application of the Shannon decomposition realizes this expansion. We can assign the function \( f .x_1; \ldots; x_n/ \) of \( n \) variables to both the negative and the positive cofactors of a Shannon decomposition with regard to \( x_{n+1} \)
\[
f(x_1, \ldots, x_n, x_{n+1} = 0) = f(x_1, \ldots, x_n) ,
\]
\[
f(x_1, \ldots, x_n, x_{n+1} = 1) = f(x_1, \ldots, x_n) ,
\]
and get as expansion
\[
f(x_1, \ldots, x_n, x_{n+1}) = \overline{x}_{n+1} f(x_1, \ldots, x_n) \lor x_{n+1} f(x_1, \ldots, x_n)
\]
the function \( f(x_1, \ldots, x_n, x_{n+1}) \) of \( n + 1 \) variables.

1.3 BOOLEAN RINGS

The algebraic structure of a ring requires an addition and a multiplication. For each Boolean space \( B^n \) there are two Boolean Rings. For the first Boolean Ring, as the addition the antivalence \( \oplus \) will be taken, the conjunction \( \land \) is used as multiplication. The second (dual) Boolean Ring uses as addition the equivalence \( \odot \) and the disjunctions \( \lor \) as multiplication. The following axioms must be satisfied.

1. Commutativity:
\[
x_1 \oplus x_2 = x_2 \oplus x_1 ,
\]
\[
x_1 \odot x_2 = x_2 \odot x_1 ,
\]

2. Associativity:
\[
x_1 \oplus (x_2 \oplus x_3) = (x_1 \oplus x_2) \oplus x_3 = x_1 \oplus x_2 \oplus x_3 ,
\]
\[
x_1 \odot (x_2 \odot x_3) = (x_1 \odot x_2) \odot x_3 = x_1 \odot x_2 \odot x_3 ,
\]

3. Zero element:
\[
x \oplus 0 = x ,
\]
\[
x \odot 1 = x ,
\]

4. Inverse element:
\[
x \oplus x = 0 ,
\]
\[
x \odot x = 1 ,
\]

5. Unit element:
\[
x \land 1 = x ,
\]
\[
x \lor 0 = x ,
\]

6. Distributivity:
\[
x_1 \land (x_2 \lor x_3) = (x_1 \land x_2) \lor (x_1 \land x_3) ,
\]
\[
x_1 \lor (x_2 \land x_3) = (x_1 \lor x_2) \land (x_1 \lor x_3) ,
\]

4. Idempotence:
\[
x \land x = x ,
\]
\[
x \lor x = x .
\]
The idempotence characterizes Boolean Rings. The comparison of the upper line in above axioms (valid for the first Boolean Ring) and the associated line below (valid for the second Boolean Ring) show both the duality of the operations \((\land \leftrightarrow \lor)\) as well as \((\oplus \leftrightarrow \ominus)\) and the opposite roles of the values 0 and 1.

**Theorem 1.10 Boolean Rings.** The structures
\[
(\mathbb{B}, \oplus, \land, 0, 1), \quad (\mathbb{B}, \ominus, \lor, 1, 0), \quad (\mathbb{B}^n, \oplus, \land, 0, 1), \quad \text{and} \quad (\mathbb{B}^n, \ominus, \lor, 1, 0)
\]
are Boolean Rings.

The rule (to be checked as before)
\[
x_1 \lor x_2 = x_1 \oplus x_2 \oplus x_1 x_2 \tag{1.50}
\]
connects antivalence and disjunction. The complement can be eliminated by
\[
\overline{x} = 1 \oplus x. \tag{1.51}
\]

A next normal form, the **antivalence normal form**, can be constructed by means of the disjunctive normal form. Since two conjunctions are always different, it is possible to find at least one variable \(x_i\) which appears non-negated in one conjunction \(C_1\) and negated in \(C_2\):
\[
C_1 = x_i C' \quad \text{and} \quad C_2 = \overline{x_i} C''.
\]

\(C_1 = 1\) and \(C_2 = 1\) hold for different vectors, therefore \(C_1 \land C_2 = 0\); such conjunctions are **orthogonal** to each other. Subsequently this concept of **orthogonality** will also be used for sets of vectors.

The property \(C_1 C_2 = 0\) simplifies the rule (1.50)
\[
C_1 \lor C_2 = C_1 \oplus C_2 \oplus C_1 C_2
\]
to
\[
C_1 \lor C_2 = C_1 \oplus C_2
\]
when the variables are replaced by conjunctions. This relationship is generalized by the following.

**Theorem 1.11 Orthogonality of Conjunctions.** Let \(C_i, i = 1, \ldots, k\), be \(k\) conjunctions. If
\[
C_i \land C_j = 0 \quad \forall i \neq j, \quad 1 \leq i, j \leq k \tag{1.52}
\]
then
\[
\bigvee_{i=1}^{k} C_i = \bigoplus_{i=1}^{k} C_i. \tag{1.53}
\]
16  1. BASICS OF BOOLEAN STRUCTURES

All conjunctions (minterms) of a disjunctive normal form are orthogonal to each other. Hence, due to Theorem 1.11 the disjunction sign of the disjunctive normal form (1.26) simply can be replaced by the antivalence without any change of the specified function:

\[
f(x_1, x_2, x_3, x_4) = \overline{x_1}x_2\overline{x_3}x_4 \oplus \overline{x_1}x_2x_3\overline{x_4} \oplus x_1\overline{x_2}\overline{x_3}x_4 \oplus x_1x_2x_3\overline{x_4} \oplus x_1x_2x_3x_4.
\]  

(1.54)

This antivalence normal form is also uniquely defined except the order of the conjunctions.

Finally, in this normal form the negation can be eliminated by using the rule (1.51), and the distributivity law (1.46) will be applied thereafter. For instance:

\[
\overline{x_1}x_2x_3x_4 = (1 \oplus x_1)x_2x_3x_4 = x_2x_3x_4 \oplus x_1x_2x_3x_4.
\]

Further simplifications might be possible with other conjunctions. If there are, for instance, two equal conjunctions then we get

\[
C_1 \oplus C_1 = 0 \quad \text{and} \quad F \oplus 0 = F.
\]

Hence, two equal conjunctions can be deleted.

In this way, the antivalence normal form (1.54) can be expressed by the positive polarity Reed-Muller polynomial:

\[
f(x_1, x_2, x_3, x_4) = x_1 \oplus x_2 \oplus x_1x_2 \oplus x_1x_3 \oplus x_1x_4 \oplus x_2x_3 \oplus x_2x_4 \oplus x_1x_2x_3 \oplus x_1x_2x_4.
\]  

(1.55)

It can be seen that the conjunctions consist of one variable, two variables, and three variables. It is a property of the transformed function \(f(x_1, x_2, x_3, x_4)\) that the conjunction of four variables does not occur in the expression (1.55).

There is also the possibility to switch between Boolean Rings and Boolean Algebras by eliminating \(\oplus\):

\[
x_1 \oplus x_2 = \overline{x_1}x_2 \lor x_1\overline{x_2}.
\]  

(1.56)

In order to transfer the conjunctive normal form into an equivalence normal form, we need the following two rules:

\[
D_1 \land D_2 = D_1 \lor D_2 \lor (D_1 \lor D_2),
\]

\[
\overline{x} = 0 \lor x.
\]  

(1.57)  

(1.58)

In the same way as has been done for the antivalence normal form it can be concluded that for two different disjunctions \(D_i\) and \(D_j\) always \(D_i \lor D_j = 1\) holds, and we get

\[
D_1 \land D_2 = D_1 \lor D_2.
\]
Theorem 1.12 Orthogonality of Disjunctions. Let $D_i, i = 1, \ldots, k$, be $k$ disjunctions. If

$$D_i \lor D_j = 0 \quad \forall i \neq j, 1 \leq i, j \leq k \quad (1.59)$$

then

$$\bigwedge_{i=1}^{k} D_i = \bigcap_{i=1}^{k} D_i \quad (1.60)$$

Remaining negated variables can be eliminated using (1.58) and the distributive law (1.47).

This second Boolean Ring $(\mathbb{B}, \odot, \lor, 1, 0)$ has the same properties as the ring with the antivalence and the conjunction $(\mathbb{B}, \oplus, \land, 0, 1)$. Therefore only the first ring will be used.

1.4 BOOLEAN EQUATIONS AND INEQUALITIES

We start this complex by an example which is easy to understand and shows the problem.

Example 1.13 Solving a Boolean Equation. Let the equation

$$x_1 \lor x_2 = x_3 \land x_4 \quad (1.61)$$

be given. Since we are dealing with Boolean functions, the equality can only have the format

$$0 = 0 \quad \text{or} \quad 1 = 1 .$$

$x_1 \lor x_2 = 0$ holds for $x_1 = 0, x_2 = 0$. $x_3 \land x_4 = 0$ holds for $x_3 = 0, x_4 = 0$; $x_3 = 0, x_4 = 1$; $x_3 = 1, x_4 = 0$; hence, we have the following set of solution vectors with the components $(x_1, x_2, x_3, x_4)$:

$$\{(0000), (0001), (0010)\} .$$

Now the identity $1 = 1$ has to be explored, and, according to the definition of $\lor$ and $\land$ we get the following solutions:

$$\{(0111), (1011), (1111)\} .$$

Altogether, this equation has six solution vectors.

Definition 1.14 Boolean Equation. Let $x = (x_1, \ldots, x_n)$, $f(x)$ and $g(x)$ be two Boolean functions, then

$$f(x) = g(x) \quad (1.62)$$
is a Boolean equation of \( n \) variables. The vector \( b = (b_1, \ldots, b_n) \) is a solution of this equation if \( f(b) = g(b) \) (i.e., \( f(b) = g(b) = 0 \) or \( f(b) = g(b) = 1 \)).

It is easily possible to reduce the considerations to homogeneous equations.

**Theorem 1.15 Homogeneous Equations.** The equation \( f(x) = g(x) \) is equivalent to the following two equations:

- homogeneous restrictive equation: \( f(x) \oplus g(x) = 0 \).
- homogeneous characteristic equation: \( f(x) \odot g(x) = 1 \).

The original equation and the two homogeneous equations have the same solution set.

It is very easy to eliminate inequalities. The inequality

\[
    f(x) \leq g(x)
\]

is equivalent to the two equations

\[
    f(x) \land \overline{g(x)} = 0,
\]

\[
    \overline{f(x)} \lor g(x) = 1.
\]

As done before, these equivalent transformations can be applied to binary vectors and particularly to Boolean functions.

### 1.5 Lists of Ternary Vectors (TVL)

The use of ternary vectors started in the 1970s by Zakrevskij [1975] and was further developed in order to create numerical methods for Boolean problems. They will be defined as a pooling of Boolean vectors.

Let two conjunctions \( x_1 x_2 x_3 x_4 \) and \( \overline{x}_1 x_2 x_3 x_4 \) be given; they are equal to 1 for the two binary vectors (1111) and (0111). This can be abbreviated by (–111). The symbol – can be replaced by 0 and by 1, the ternary vector represents two binary vectors.

In the background the laws of a Boolean Algebra are used:

\[
    x_1 x_2 x_3 x_4 \lor \overline{x}_1 x_2 x_3 x_4 = (x_1 \lor \overline{x}_1) x_2 x_3 x_4 = x_2 x_3 x_4 .
\]

The resulting conjunction is equal to 1 for \( x_2 = x_3 = x_4 = 1 \) and any value of \( x_1 \).

When a function is given by a disjunctive form (i.e., several conjunctions are combined by \( \lor \)), then each conjunction will be translated into a ternary vector, and the different ternary vectors are collected in a list or matrix (TVL).

**Example 1.16 TVL of a Boolean Function in Disjunctive Form.** The TVL

\[
    D(f) = \begin{array}{ccc}
    x_1 & x_2 & x_3 \\
    1 & 0 & 0 \\
    0 & 1 & 1 \\
    0 & 0 & 1 \\
    \end{array}
\]
represents the disjunctive form of the function
\[ f(x_1, x_2, x_3) = x_1 \overline{x}_3 \lor x_2 x_3 \lor x_1 \overline{x}_2 x_3. \]
The set of all Boolean vectors \( x \) with \( f(x) = 1 \) is collected in this list.

When we look at the function \( f(x_1, x_2, x_3, x_4) = x_1 \lor x_2 \lor x_3 \) in \( \mathbb{B}^4 \) then we get in a first step three ternary vectors, the respective sets of Boolean vectors, however, overlap each other.

\[
D(f) = \begin{array}{cccc}
1 & - & - & - \\
- & 1 & - & - \\
- & - & 1 & - \\
\end{array} \quad (1.69)
\]

This is an uncomfortable situation and can be avoided when we introduce the orthogonality of ternary vectors.

**Definition 1.17 Orthogonality.** Let \( S(t) \) be the set of all \( x \in \mathbb{B}^n \) which can be generated by means of the ternary vector \( t \). Two vectors \( t_1 \) and \( t_2 \) are orthogonal to each other \( (t_1 \perp t_2) \) if \( S(t_1) \cap S(t_2) = \emptyset \).

**Theorem 1.18 Orthogonality.** The property \( t_1 \perp t_2 \) holds if and only if for at least one component \( i \) the combination \( t_{1,i} = 0, t_{2,i} = 1 \) or \( t_{1,i} = 1, t_{2,i} = 0 \) (1.70) exists.

This very useful property can easily be established and tested. The orthogonal TVL

\[
ODA(f) = \begin{array}{cccc}
1 & - & - & - \\
0 & 1 & - & - \\
0 & 0 & 1 & - \\
\end{array} \quad (1.71)
\]
generates the same set of Boolean vectors as (1.69). The form predicate ODA indicates that this TVL can, due to Theorem 1.11, alternatively be used to describe a Boolean function in disjunctive form \( D(f) \) or in antivalence form \( A(f) \).

**SUMMARY**

In this chapter we discussed very briefly some important terms of Boolean Algebras. The Boolean spaces \( \mathbb{B}^n \) are built from the elements \( 0 \) and \( 1 \) or vectors of these elements. Boolean functions are unique mappings from \( \mathbb{B}^n \) into \( \mathbb{B} \). Boolean expressions of variables and operations describe in a compact manner Boolean functions. A Boolean equation will be built from two Boolean functions and has a set of Boolean vectors as solution. The Boolean Algebra is widely used to specify, design, analyze, and test digital circuits and systems.
1.1 Use the table method to prove the associative law (1.4).

1.2 Determine the function table of the function:

\[ f(x_1, x_2, x_3, x_4) = (x_1 \lor x_2) \land ((x_1 \oplus x_3) \lor (x_2 \oplus x_4)). \]

1.3 A lattice of Boolean functions is specified by Table 1.8 which contains three don't-care values \( \Phi \).

(a) How many functions belong to this lattice?
(b) Describe each function of this lattice by a formula in disjunctive normal form.
(c) Apply the idempotence law (1.5) and the absorption law (1.8) to find simplified disjunctive forms of these functions.
(d) Find all pairs of functions of this lattice for which the conjunction results in the minimum and the disjunction in the maximum of all these functions.
(e) Which function of this lattice has the simplest formula in disjunctive form?

1.4 Which binary vectors belong to the solution of the Boolean equation:

\[ (x_1 \lor x_3) \land x_2 = (x_3 \oplus x_4) \lor x_1. \]

Specify the solution set \( S \):

(a) by a list of binary vectors (BVL), and
1.5 The following TVL is not orthogonal.

\[
\begin{array}{cccc}
  x_1 & x_2 & x_3 & x_4 \\
  1 & - & 0 & 0 \\
  - & 1 & 1 & - \\
  0 & - & 0 & - \\
  - & - & 1 & 1 \\
\end{array}
\]  

(1.74)

(a) Which ternary vectors of the TVL (1.74) are not orthogonal to each other?

(b) Assume that the TVL (1.74) represents a function in disjunctive form. Construct the associated ODA-form.

(c) Assume that the TVL (1.74) represents a function in antivalence form. Construct the associated ODA-form.
